

prompt:

[Target persona: <elem_low> — elementary, lower]

A baker bakes 24 muffins and shares them equally among 6 friends. How many muffins does each friend get?

initial_reasoning_steps:

Step 1: We start with 24 muffins to share among 6 friends.

Step 2: Sharing equally means splitting 24 into 6 equal groups.

Step 3:

chosen_step (persona-appropriate):

We split 24 into 6 equal groups: $24 \div 6 = 4$.

So each friend gets 4 muffins.

rejected_step (persona drift):

Let x be the unknown variable and solve the linear equation $6x = 24$, giving $x = 4$.

(Uses algebra / variable / equation — outside an elementary learner's register, even though the math is correct.)

Figure 1-b. A belief-conditional preference sample: at the same prefix, the rejected step drifts from the target persona's register.
